September 9, 2019

https://github.com/affeldt-aist/succinct

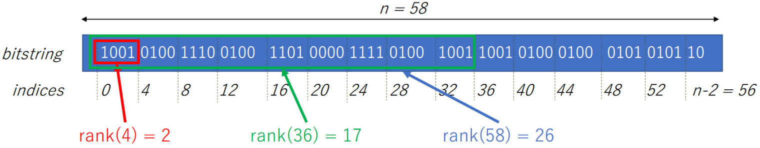
Succinct Data Structures

- Representation optimized for both time and space
- *"Compression without need to decompress"*
- Much used for Big Data
- Application examples
  - Compression for Data Mining
  - Google's Japanese IME

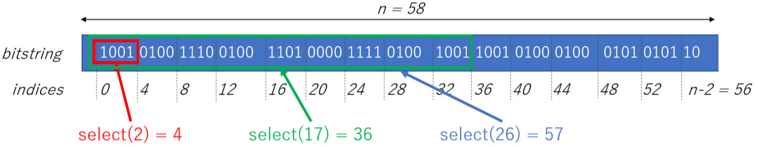
Rank and Select

To allow fast access, two primitive functions are heavily optimized. They can be computed in constant time.

- rank(i) = number of 1's up to position i



- select(i) = position of the i^{th} 1: rank(select(i)) = i



Certified implementation of rank [Tanaka A., Affeldt, Garrigue 2016]

Coq definitions

rank counts occurrences of (b : T).

```
Definition rank i (s : list T) :=
  count_mem b (take i s).
```

select is its (minimal) inverse.

```
Definition select i (s : list T) : nat :=
  index i [seq rank k s | k <- iota 0 (size s).+1].
```

pred s y is the last b before y (included).

```
Definition pred s y := select (rank y s) s.
```

succ s y is the first b after y (included).

```
Definition succ s y := select (rank y.-1 s).+1 s.
```

Getting the indexing right is challenging.
Here indices start from 1, but there is no fixed convention.

Today's story

Trees in Succinct Data Structures

Featuring two views

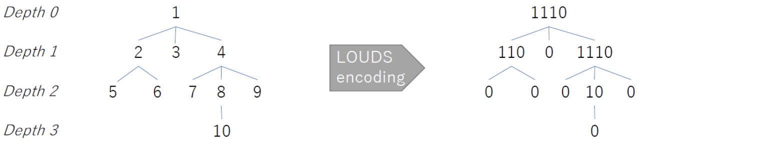
Tree as sequence Encode the structure of a tree as a bit sequence, providing efficient navigation through rank and select

Sequence as tree Balanced trees (here red-black) can be used to encode dynamic bit sequences

- Both implemented and proved in Coq/SSReflect
- They can be combined together

L.O.U.D.S.

Level-**O**rder **U**nary **D**egree **S**equence
[Navarro 2016, Chapter 8]



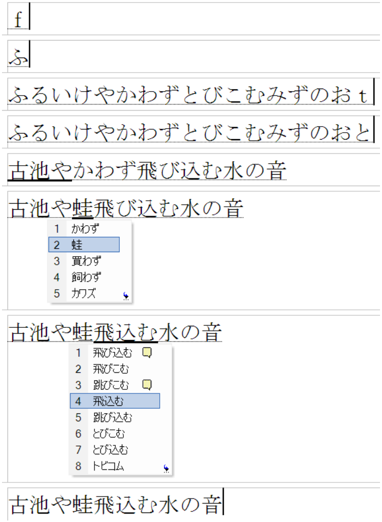
Depth 0	*Depth 1*	*Depth 2*	*Depth 3*
1	234	56789	10

Depth 0	*Depth 1*	*Depth 2*	*Depth 3*
1110	11001110	000100	0

- Unary coding of node arities, put in breadth-first order
- Each node of arity a is represented by a 1's followed by 0
- The structure of a tree uses just $2n$ bits
- Useful for dictionaries (e.g. Google Japanese IME)

What is a Japanese IME ?

- Incremental input
- Select a word in the dictionary according to a prefix



Implementation of primitives

Navigation primitives work by moving inside the LOUDS

The basic operations are

- Position of the i^{th} child of a node
- Position of its parent
- Number of children

```
Variable B : list bool.  (* our LOUDS *)

Definition LOUDS_child v i :=
  select false (rank true (v + i) B).+1 B.
Definition LOUDS_parent v :=
  pred false B (select true (rank false v B) B).
Definition LOUDS_children v :=
  succ false B v.+1 - v.+1.
```

  The position w of the branch leading to this node.
- `pred false B w` $= 4$ for $w = 6$
  The position w' of the node containing this branch.

Functional correctness

Assume an isomorphism LOUDS_position between valid paths in the tree, and valid positions in the LOUDS.
Our 3 primitives shall satisfy the following invariants.

```
Definition LOUDS_position (t : tree A) (p : list nat) : nat.
Variable t : tree A.
Let B := LOUDS t.

Theorem LOUDS_childE (p : list nat) (x : nat) :
  valid_position t (rcons p x) ->
  LOUDS_child B (LOUDS_position t p) x = LOUDS_position t (rcons p x).

Theorem LOUDS_parentE (p : list nat) (x : nat) :
  valid_position t (rcons p x) ->
  LOUDS_parent B (LOUDS_position t (rcons p x)) = LOUDS_position t p.

Theorem LOUDS_childrenE (p : list nat) :
  valid_position t p ->
  children t p = LOUDS_children B (LOUDS_position t p).
```

How do we prove it ?

First attempt

Define traversal by recursion on the height of the tree.

```
Fixpoint LOUDS' n (s : forest A) :=
  if n is n'.+1 then
    map children_description s ++ LOUDS' n' (children_of_forest s)
  else [::].
Definition LOUDS (t : tree A) := flatten (LOUDS' (height t) [:: t]).

Definition LOUDS_position (t : tree A) (p : list nat) :=
  lo_index t p    +    (lo_index t (rcons p 0)).-1.
(* number of 0's            number of 1's              *)

Theorem LOUDS_positionE t (p : list nat) :
  let B := LOUDS t in valid_position t p ->
  LOUDS_position t p = foldl (LOUDS_child B) 0 p.
```

`lo_index t p` is the number of valid paths preceding `p` in breadth first order.

First attempt

Success ! Could prove the correctness of all primitives.

First attempt

Success ! Could prove the correctness of all primitives.

Various problems

- Breadth first traversal does not follow the tree structure
- Cannot use structural induction
- No natural correspondence to use in proofs
- Oh, the indices!

As a result

- LOUDS related proofs took more than 800 lines
- Many lemmas had proofs longer than 50 lines
- There should be a better approach...

Perspectives

Second try

- Introduce traversal up to a path : `lo_traversal_lt`
  Generalization of `lo_index`, returning a list
- For easy induction, work on forests rather than trees
- A generating forest need not be on the same level!

Traversal and Remainder

Parameters of the traversal

```
Variables (A B : Type) (f : tree A -> B).
```

Traversal of the nodes preceding path p

```
Fixpoint lo_traversal_lt (s : forest A) (p : list nat) : list B.
```

Generating forest for nodes following path p, aka fringe

```
Fixpoint lo_fringe (s : forest A) (p : list nat) : forest A.
```

Relation between traversal and fringe

```
Lemma lo_traversal_lt_cat s p1 p2 :
  lo_traversal_lt s (p1 ++ p2) =
  lo_traversal_lt s p1 ++ lo_traversal_lt (lo_fringe s p1) p2.
```

All paths lead to Rome, i.e. complete traversals are all equal

```
Theorem lo_traversal_lt_max t p :
  size p >= height t ->
  lo_traversal_lt [:: t] p = lo_traversal_lt [:: t] (nseq (height t) 0).
```

Path, index, and position in LOUDS

Index of a node in level-order, using the traversal

```
Definition lo_index s p := size (lo_traversal_lt id s p).
```

`LOUDS_lt` generates the LOUDS as a path-indexed traversal

```
Definition LOUDS_lt s p :=
  flatten (lo_traversal_lt children_description s p).
```

Use it to define the position of a node in the LOUDS

```
Definition LOUDS_position s p := size (LOUDS_lt s p).
```

Main lemmas : relate position in LOUDS and index in traversal.
Suffix `p'` allows completion to the whole `LOUDS t`.

```
Lemma LOUDS_position_select s p p' :
  valid_position (head dummy s) p ->
  LOUDS_position s p = select false (lo_index s p) (LOUDS_lt s (p ++ p')).

Lemma lo_index_rank s p p' n :
  valid_position (head dummy s) (rcons p n) ->
  lo_index s (rcons p n) =
  size s + rank true (LOUDS_position s p + n) (LOUDS_lt s (p ++ n :: p')).
```

LOUDS perspectives

Advantages of the new approach

- Could prove naturally all invariants
- All proofs are by induction on paths
- Common lemmas arise naturally
- Only about 500 lines in total, long proofs about 20 lines

Remaining problems

- There are still longish lemmas (`lo_index_rank`, ...)
- Paths all over the place

Future work

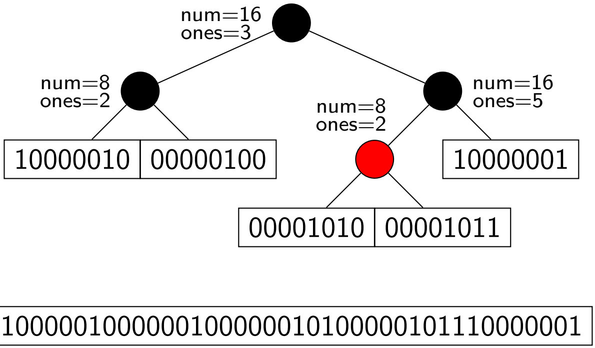
- Can we apply that to other breadth-first traversals ?

Dynamic succinct data structures

- Succinct data that can be updated (insertion/deletion)
- Concrete use cases: e.g. update in a dictionary
- Optimal static representation do not support updates. We cannot have both constant time rank/select and efficient insertion/deletion
- Using balanced trees, all operations are $O(\log n)$

[Navarro 2016, Chapter 12]

Dynamic bit sequence as tree



- *num* is the number of bits in the left subtree
- *ones* is the number of 1's in the left subtree

Implementation

- Used red-black trees to implement
  - complexity is the same for all balanced trees
  - easy to represent in a functional style
  - already several implementations in Coq
  - however we need a different data layout with new invariants, so we had to reimplement
- Two implementations using types differently
  1. simply typed implementations, with invariants expressed as separate theorems
  2. dependent types, directly encoding all the required invariants (explained yesterday in Coq workshop)
- We implemented rank, select, insert and delete

Simply typed implementation

A red-black tree for bit sequences

```
Inductive color := Red | Black.
Inductive btree (D A : Type) : Type :=
| Bnode of color & btree D A & D & btree D A
| Bleaf of A.
Definition dtree := btree (nat * nat) (list bool).
```

The meaning of the tree is given by `dflatten`

```
Fixpoint dflatten (B : dtree) :=
  match B with
  | Bnode _ l _ r => dflatten l ++ dflatten r
  | Bleaf s => s
  end.
```

Invariants on the internal representation

```
Variables low high : nat.
Fixpoint wf_dtree (B : dtree) :=
  match B with
  | Bnode _ l (num, ones) r => [&& num == size (dflatten l),
      ones == count_mem true (dflatten l), wf_dtree l & wf_dtree r]
  | Bleaf arr => low <= size arr < high
  end.
```

Introduction
Rank&Select
Plan
LOUDS
Primitives
First attempt
Second try
Perspectives
Dynamic data
Principle
Simply typed
Perspectives

Basic operations

```
Fixpoint drank (B : dtree) (i : nat) := match B with
  | Bnode _ l (num, ones) r =>
    if i < num then drank l i else ones + drank r (i - num)
  | Bleaf s => rank true i s
  end.

Lemma drankE (B : dtree) i :
  wf_dtree B -> drank B i = rank true i (dflatten B).
Proof. move=> wf; move: B wf i. apply: dtree_ind. (* ... *) Qed.

Fixpoint dselect_1 (B : dtree) (i : nat) := match B with
  | Bnode _ l (num, ones) r =>
    if i <= ones then dselect_1 l i else num + dselect_1 r (i - ones)
  | Bleaf s => select true i s
  end.
Lemma dselect_1E B i :
  wf_dtree B -> dselect_1 B i = select true i (dflatten B).
```

where dtree_ind is a custom induction principle.

All proofs are only a few lines long.

Insertion

```
Definition dins_leaf s b i :=
  let s' := insert1 s b i in (* insert bit b in s at position i *)
  if size s + 1 == high then
    let n := size s' %/ 2 in
    let sl := take n s' in let sr := drop n s' in
    Bnode Red (Bleaf _ sl) (n, count_mem true sl) (Bleaf _ sr)
  else Bleaf _ s'.

Fixpoint dins (B : dtree) b i : dtree := match B with
  | Bleaf s => dins_leaf s b i
  | Bnode c l d r =>
     if i < d.1 then balanceL c (dins l b i) r (d.1.+1, d.2 + b)
                else balanceR c l (dins r b (i - d.1)) d
  end.

Definition dinsert B b i : dtree := blacken (dins B b i).
```

The real work is in balanceL/balanceR

Balancing

- Number of cases is the main difficulty for red-black trees
- Expanding balanceL generates 11 cases
- Following SSReflect style, we avoid opaque automation

```
Ltac decompose_rewrite :=
  let H := fresh "H" in
  case/andP || (move=>H; rewrite ?H ?(eqP H)).

Lemma balanceL_wf c (l r : dtree) :
  wf_dtree l -> wf_dtree r -> wf_dtree (balanceL c l r).
Proof.
case: c => /= wfl wfr. by rewrite wfl wfr ?(dsizeE,donesE,eqxx).
case: l wfl =>
  [[[[] lll [lln llo] llr|llA] [ln lo] [[] lrl [lrn lro] lrr|lrA]
   |ll [ln lo] lr]|lA] /=;
  rewrite wfr; repeat decompose_rewrite;
  by rewrite ?(dsizeE,donesE,size_cat,count_cat,eqxx).
Qed.
```

Properties of insertion

Functional correctness

```
Lemma dinsertE (B : dtree) b i : wf_dtree' B ->
  dflatten (dinsert B b i) = insert1 (dflatten B) b i.
```

Well-formedness and red-black invariants

```
Lemma dinsert_wf (B : dtree) b i :
  wf_dtree' B -> wf_dtree' (dinsert B b i).
Lemma dinsert_is_redblack (B : dtree) b i n :
  is_redblack B Red n ->
  exists n', is_redblack (dinsert B b i) Red n'.
```

where

- `wf_dtree'` is needed for small sequences

```
Definition wf_dtree' t :=
  if t is Bleaf s then size s < high else wf_dtree low high t.
```

- `is_redblack` checks the red-black tree invariants:
    - the child of a red node cannot be red
    - both children have the same black depth

Deletion

The mysterious side

- Omitted in Okasaki's Book
- Enigmatic algorithm by Stefan Kahrs, with an invariant but no details

Chose to rediscover it

- Started with dependent types, guessing invariants
- Used extraction to retrieve the computational part
- Rewrote and proved the simply typed version
  Proofs are small, but use `Ltac` for repetitive cases.
- As case analysis generates hundreds of cases, performance can be a problem.

```
Lemma ddelete_is_redblack B i n :
  is_redblack B Red n -> exists n', is_redblack (ddel B i) Red n'.
```

Dynamic bit sequence perspectives

- Simply typed approach
  - SSReflect style worked well, providing short and maintainable proofs
  - could obtain proofs of balancing without complex machinery (just automatic case analysis)
  - however many small lemmas are required
- Dependently typed version
  - all properties are in the types, no need for dispersed proofs
  - Coq support not perfect yet
- Future work
  - We have not yet started working on complexity
  - We also need to extract efficient implementations

https://github.com/affeldt-aist/succinct
